DIP COATING

Dip coating is usually used if either the type or size of the substrates to be coated are neither suitable for spin-coating nor spray coating; or the photoresist represents a significant cost factor and requires a reduction of resist consumption per substrate.

This chapter describes the technology of dip coating and gives explanations and answers to common problems relating to this coating technique.

Principle of Dip Coating

Basic Principle of Dip Coating

During dip coating, the substrate is usually vertically lifted out of a cuvette filled with resist. The solvent-rich resist film just formed thins out in the solvent-saturated atmosphere above the resist level. In the saturated solvent atmosphere directly above the resist bath (Fig. 63), the formed resist film first flows downward.

Only when enough solvent has evaporated from the resist film does the thinning end. Thus, the resist film thickness can be adjusted by means of the dwell time of the resist film in the saturated solvent atmosphere and thus the drawing speed of the substrate (high drawing speed = high resist film thickness).

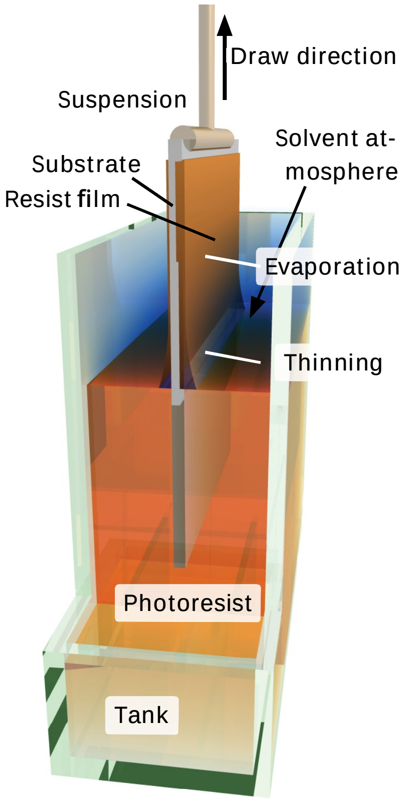

Fig. 63: Schematic representation of the dip-coating of a substrate with photoresist

Possible Advantages

Dip coating is a suitable coating technique when the substrate size, weight or geometry make spin coating difficult or impossible to realize.

The high resist yield of dip coating (100 % or, respectively, 50 % if only one substrate side needs to be coated with resist) may be important if resist consumption is a significant expense factor. However, one has to consider the fact that a certain resist volume is required to fill the cuvette the first time. Due to the high resist yield, an exchange of the resist volume in the tank might also be necessary when the resist in the tank expires before it's consumed.

Limitations

Dip coating is not suitable for applications where a double-side coating of the substrate or coating of holes or trenches in the substrate are undesirable which can hardly be avoided from a technical aspect.

Substrates with strong textures or macroscopic three-dimensional components on which larger amounts of resist can flow over the substrate which has just been coated are also problematic by means of a sufficiently high resist film homogeneity over the entire substrate.

Dip Coating Techniques

The vertical drawing out of a cuvette is an option in the case of separate, mechanically rigid substrates. A continuous *roll-to-roll* coating can also be used for the coating of films, in which the substrate is drawn from a roll through a basin filled with resist and is rewound onto a roll after subsequent drying.

Requirements for the Equipment

The Tank

In order to minimize the required resist volume and to maintain a constant solvent atmosphere above the liquid resist, the cuvette - the tank for the photoresist - containing the resist should be no more than a few cm larger (in all three directions) than the substrate to be coated. For this reason, flat substrates such as metal sheets or wafers require a narrow cuvette design. Increasing the cuvette size does not affect the coating result but increases the resist volume required to start with as well as the lifetime of each filling. This also has to be taken into consideration if no large-scale series production is scheduled, thus the resist expired before consumed has to be exchanged.

In the case of a *roll-to-roll* coating, it is recommended for cost reasons to estimate in the definition of the resist volume in the tank what resist amount is needed within the resist expiry date for coating.

The walls and seals must be permanently chemically stable against the solvents used in the resist, which is usually met by Teflon, HD-PE or stainless steel among other materials.

For longer breaks between the coatings, a tightly closing lid covering the resist tank minimises the evaporation of solvents from the cuvette or the entry of particles.

Filling with Photoresist and Shelf Life

After filling the tank with resist, wait at least a few hours (e. g. overnight) before the first coating step to outgas the air bubbles hereby incorporated into the resist. If the first coated substrates nevertheless show lots of defects, there are probably still bubbles in the resist.

Dip coating resists are often highly diluted, which – especially at room temperature – reduces the shelf life. 3 - 6 months after the cuvette has been filled with fresh resist, it might be necessary to exchange the entire(!) volume so as not to carry a part of the expired resist from one filling to the next.

A measurement of the concentration of the low-boiling, more volatile solvent, carried out in certain cycles, allows a timely addition of the amount lost by evaporation. Such a measurement or at least estimation can take place either via the viscosity of the resist or its density, since low-boiling solvents such as acetone or MEK usually have a significantly lower density than the resist in its original composition.

Substrate Suspension

The upper substrate suspension should not dip into the resist in the tank. Otherwise, the resist will drain off the suspension over the already-coated substrate and thereby cause strong inhomogeneities in the resist film thickness.

Motor and Motor Control

The motor lifting the substrate should operate continuously and work vibration-free. Otherwise the resist film thickness will show characteristic horizontal, line-like inhomogeneities. For the same reason, the entire dip coater should be vibration-free and the air stream around the dip coater remain constant. The realisable drawing speed should range from approx. 1 - 20 mm/s, typical drawing speeds are 3 - 10 mm/s for resist film thicknesses of several µm.

Operational Safety from Particles

The atmosphere in the room the dip coater is placed should be particle-free as possible, since any impurities accumulate in the cuvette over weeks and months, and even in the case of less critical processes can decrease the yield by defects in the coated film.

Between the coatings, a lid minimises the evaporation of solvents from the cuvette or the entry of particles.

Photoresist for Dip Coating

When selecting a dip coating resist that is most suitable for a specific application, the essential criterion is whether a positive, image reversal or negative resist is to be applied and with which resolution for which application the developed resist mask is to be used.

The solvent composition of the resist is decisive for the coating result: Low-boiling solvents increase the viscosity of the just formed resist film within seconds and thus prevent too much flow of the resist over the substrate. High-boiling solvents prevent a too rapid complete drying and thus allow smoothing of the resist film within minutes at room temperature.

We offer optimised photoresists for different applications for dip coating - please contact us if you are interested!

Our Photoresists: Application Areas and Compatibilities

	Recommended Applications [1]	Resist Family	Photoresists	Resist Film Thickness [2]	Recommended Developers [3]	Recommended Removers [4]
Positive	Improved adhesion for wet etching, no focus on steep resist sidewalls	AZ® 1500	AZ® 1505 AZ® 1512 HS AZ® 1514 H AZ® 1518	≈ 0.5 µm ≈ 1.0 - 1.5 µm ≈ 1.2 - 2.0 µm ≈ 1.5 - 2.5 µm	AZ® 351B, AZ® 326 MIF, AZ® 726 MIF, AZ® Developer	AZ® 100 Remover, TechniStrip® P1316 TechniStrip® P1331

[1] In general, almost all resists can be used for almost any application. However, the special properties of each resist family makes them specially suited for certain fields of application.

[2] Resist film thickness achievable and processable with standard equipment under standard conditions. Some resists can be diluted for lower film thicknesses; with additional effort also thicker resist films can be achieved and processed.

[3] Metal ion free (MIF) developers are significantly more expensive, and reasonable if metal ion free development is required.

Our Developers: Application Areas and Compatibilities

Inorganic Developers

(typical demand under standard conditions approx. 20 L developer per L photoresist)

AZ® Developer is based on sodium phosphate and –metasilicate, is optimized for minimal aluminum attack and is typically used diluted 1 : 1 in DI water for high contrast or undiluted for high development rates. The dark erosion of this developer is slightly higher compared to other developers.

AZ® 351B is based on buffered NaOH and typically used diluted 1 : 4 with water, for thick resists up to 1 : 3 if a lower contrast can be tolerated.

AZ® 400K is based on buffered KOH and typically used diluted 1 : 4 with water, for thick resists up to 1 : 3 if a lower contrast can be tolerated.

AZ® 303 specifically for the AZ® 111 XFS photoresist based on KOH / NaOH is typically diluted 1 : 3 - 1 : 7 with water, depending on whether a high development rate, or a high contrast is required

Metal Ion Free (TMAH-based) Developers

(typical demand under standard conditions approx. 5 - 10 L developer concentrate per L photoresist)

AZ® 326 MIF is 2.38 % TMAH- (TetraMethylAmmoniumHydroxide) in water.

AZ® 726 MIF is 2.38 % TMAH- (TetraMethylAmmoniumHydroxide) in water, with additional surfactants for rapid and uniform wetting of the substrate (e. g. for puddle development)

AZ® 826 MIF is 2.38 % TMAH- (TetraMethylAmmoniumHydroxide) in water, with additional surfactants for rapid and uniform wetting of the substrate (e. g. for puddle development) and other additives for the removal of poorly soluble resist components (residues with specific resist families), however at the expense of a slightly higher dark erosion.

Our Removers: Application Areas and Compatibilities

AZ® 100 Remover is an amine solvent mixture and standard remover for AZ® and TI photoresists. To improve its performance, AZ® 100 remover can be heated to 60 - 80°C. Because the AZ® 100 Remover reacts highly alkaline with water, it is suitable for this with respect to sensitive substrate materials such as Cu, Al or ITO only if contamination with water can be ruled out..

TechniStrip® P1316 is a remover with very strong stripping power for Novolak-based resists (including all AZ® positive resists), epoxy-based coatings, polyimides and dry films. At typical application temperatures around 75°C, TechniStrip® P1316 may dissolve cross-linked resists without residue also, e.g. through dry etching or ion implantation. TechniStrip® P1316 can also be used in spraying processes. For alkaline sensitive materials, TechniStrip® P1331 would be an alternative to the P1316. Not compatible with Au.

TechniStrip® P1331 can be an alternative for TechniStrip® P1316 in case of alkaline sensitive materials. TechniStrip® P1331 is not compatible with Au.

TechniStrip® NI555 is a stripper with very strong dissolving power for Novolak-based negative resists such as the AZ® 15 nXT and AZ® nLOF 2000 series and very thick positive resists such as the AZ® 40 XT. TechniStrip® NI555 was developed not only to peel cross-linked resists, but also to dissolve them without residues. This prevents contamination of the basin and filter by resist particles and skins, as can occur with standard strippers. TechniStrip® NI555 is not compatible with GaAs.

TechniClean™ CA25 is a semi-aqueous proprietary blend formulated to address post etch residue (PER) removal for all interconnect and technology nodes. Extremely efficient at quickly and selectively removing organo-metal oxides from Al, Cu, Ti, TiN, W and Ni.

TechniStrip™ NF52 is a highly effective remover for negative resists (liquid resists as well as dry films). The intrinsic nature of the additives and solvent make the blend totally compatible with metals used throughout the BEOL interconnects to WLP bumping applications.

TechniStrip™ Micro D2 is a versatile stripper dedicated to address resin lift-off and dissolution on negative and positive tone resist. The organic mixture blend has the particularity to offer high metal and material compatibility allowing to be used on all stacks and particularly on fragile III/V substrates for instance.

TechniStrip™ MLO 07 is a highly efficient positive and negative tone photoresist remover used for IR, III/V, MEMS, Photonic, TSV mask, solder bumping and hard disk stripping applications. Developed to address high dissolution performance and high material compatibility on Cu, Al, Sn/Ag, Alumina and common organic substrates.

Our Wafers and their Specifications

Silicon-, Quartz-, Fused Silica and Glass Wafers

Silicon wafers are either produced via the Czochralski- (CZ-) or Float zone- (FZ-) method. The more expensive FZ wafers are primarily reasonable if very high-ohmic wafers (> 100 Ohm cm) are required.

Quartz wafers are made of monocrystalline SiO_2, main criterion is the crystal orientation (e. g. X-, Y-, Z-, AT- or ST-cut)

Fused silica wafers consist of amorphous SiO_2. The so-called JGS2 wafers have a high transmission in the range of ≈ 280 - 2000 nm wavelength, the more expensive JGS1 wafers at ≈ 220 - 1100 nm.

Our glass wafers, if not otherwise specified, are made of borosilicate glass.

Specifications

Common parameters for all wafers are diameter, thickness and surface (1- or 2-side polished). Fused silica wafers are made either of JGS1 or JGS2 material, for quartz wafers the crystal orientation needs to be defined. For silicon wafers, beside the crystal orientation (<100> or <111>) the doping (n- or p-type) as well as the resistivity (Ohm cm) are selection criteria.

Prime- ,Test-, and Dummy Wafers

Silicon wafers usually come as „Prime-grade“ or „Test-grade“, latter mainly have a slightly broader particle specification. „Dummy-Wafers“ neither fulfill Prime- nor Test-grade for different possible reasons (e. g. very broad or missing specification of one or several parameters, reclaim wafers, no particle specification) but might be a cheap alternative for e. g. resist coating tests or equipment start-up.

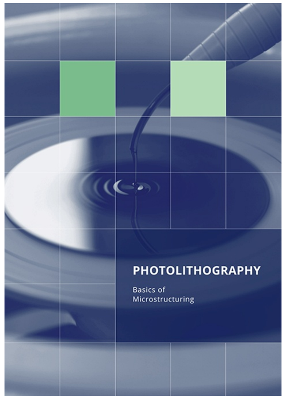
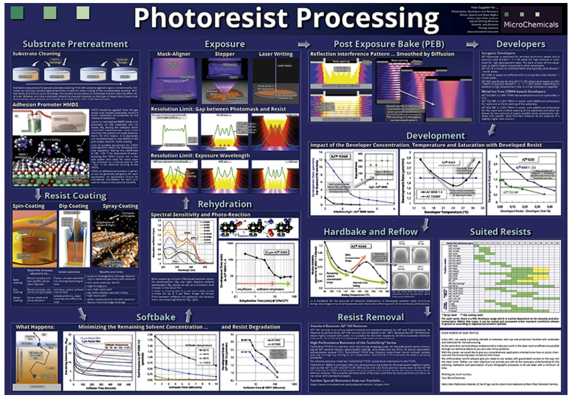
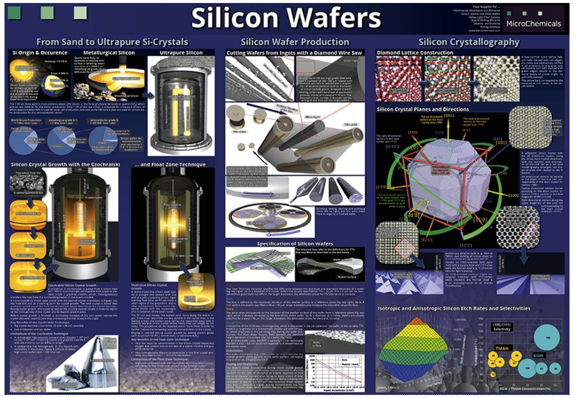
Our Photolithography Book and -Posters







We see it as our main task to make you understand all aspects of microstructuring in an application-oriented way.

At present, we have implemented this claim with our book **Photolithography** on over 200 pages, as well as attractively designed DIN A0 posters for your office or laboratory.

We will gladly send both of these to you free of charge as our customer (if applicable, we charge shipping costs for non-European deliveries):

www.microchemicals.com/downloads/brochures.html

www.microchemicals.com/downloads/posters.html

Thank you for your interest!

Disclaimer of Warranty & Trademarks

All information, process descriptions, recipes, etc. contained in this book are compiled to the best of our knowledge. Nevertheless, we can not guarantee the correctness of the information. Particularly with regard to the formulations for chemical (etching) processes we assume no guarantee for the correct specification of the components, the mixing conditions, the preparation of the batches and their application.

The safe sequence of mixing components of a recipe usually does not correspond to the order of their listing. We do not warrant the full disclosure of any indications (among other things, health, work safety) of the risks associated with the preparation and use of the recipes and processes. The information in this book is based on our current knowledge and experience. Due to the abundance of possible influences in the processing and application of our products, they do not exempt the user from their own tests and trials. A guarantee of certain properties or suitability for a specific application can not be derived from our data.
