PROCESSING OF AZ® NEGATIVE RESISTS

With negative resists, in contrast to positive resists, the non-exposed areas are developed away, the exposed areas remain after development. Thus negative resists show a similar behaviour as image reversal resists in the negative mode, but with a significant difference: In contrast to most reversal resists, the exposed negative resists cross-link which impacts their chemical and thermal stability, but also the possibilities of removing the resist structures at the end of the lithography process.

Exposure

Spectral Sensitivity:
The AZ® nLOF 2000 negative resist series as well as the AZ® 15 nXT and 125 nXT are i-line resists with a sensitivity in the wavelength range of approx. 340 - 380 nm. However, the g- and h-line need not be filtered out during the exposure, these wavelengths are largely transmitted by the resist film.

Chemical Amplification
The AZ® 15 and 125 nXT are chemically amplified, i.e. several cross-linking reactions are carried out in the resist per absorbed photon. The absorption coefficient of the resist can thus be kept so low that even very thick resist films of a few 10 μm (in the case of the AZ® 15 nXT) up to several 100 μm (AZ® 125 nXT) can be exposed with moderate light doses.

Light Dose
A too low light dose leads to an incomplete cross-linking or, in the case of optically thick resist films, the cross-linking does not reach the substrate. This increases the erosion of the exposed resist structures in the developer, but this may be desirable in the case of lift-off processes for the resist areas to form a negative resist profile near the substrate.
In the case of over-exposure, resist areas are also exposed and cross-linked by diffraction, scattering or reflection on the substrate, which should remain nominally unexposed. As a result, the developed resist structures are widened to the effect that narrow openings can no longer be cleared during development.

Bleaching
Contrary to DNQ-based resists, AZ® negative resists do not bleach. With the rel. strong absorbing AZ® nLOF 2000 resists with an i-line penetration depth of 1 - 2 μm, this manifests itself in the impossibility of exposing thick resist films of approx. >10 μm towards the substrate. As a result, the resist areas in the vicinity of the substrate do not cross-link, remain soluble in the developer, and thus allow an especially advantageous resist profile which is progressively undercut for lift-off processes.

Post Exposure Bake

Processes in the Resist Layer
In the resists of the AZ® nLOF 2000 series or the AZ® 15 nXT, the exposure activates a melamine crosslinker, which in a subsequent baking step (Post Exposure Bake, PEB) affects the linking of short phenolic resin molecules to longer chains. Without the PEB, no appreciable cross-linking takes place, that is, in the developer, the exposed resist areas would be dissolved at a similar rate as the unexposed resist.
With the AZ® 125 nXT, the exposure starts a photo polymerisation of acrylic monomers already at room temperature. This resist does not require a post exposure bake.

Bake Parameters
The recommended PEB parameters of temperature and time depend on the photoresist used and are typically 110 - 125°C for 1 - 2 minutes.
The cooler or shorter the baking, the weaker the degree of cross-linking and the greater the erosion of the exposed resist areas later in the developer.
In the case of excessively high temperatures or too long PEB times, a thermal cross-linking of non-exposed resist areas takes place, which thus can be developed much more slowly. In the case of the desire
As in the image reversal baking step of image reversal resists (see previous chapter), the PEB temperature usually should be kept constant at ±1 - 2°C for stable negative resist processes during defined times. This condition is difficult to maintain when baking in ovens, which is why the use of a hotplate is strongly recommended at least for critical processes.

With the use of a hotplate, the temperature progression attained on the substrate surface (= in the resist film) is sensitive to the nature of the substrate. Therefore, the post exposure baking parameters should be optimised individually when using massive or poorly thermally conductive substrates, or a gap between hotplate and substrate.

**Developing, Lift-off and Stripping**

**Appropriate Developers**

For the above mentioned AZ® negative resists, we recommend TMAH-based developers such as AZ® 326, 726 or 826 MIF, as well as the AZ® 303. NaOH - or KOH-based developers such as AZ® 351 B or 400 K while work well enough in some cases, cannot generally be recommended as first choice.

**Appropriate Strippers**

Organic solvents such as NMP or DMSO, are generally suitable for removing the resist film, but conventional strippers, such as the AZ® 100 Remover can also be used if the degree of cross-linking is not too high. Depending on the thickness of the resist film and the degree of cross-linking, these substances should be heated to 60 - 80°C.

Especially in the case of highly cross-linked films, the TechniStrip® products are much more suitable as stripper or lift-off medium. Additionally, support by a ultrasonic bath may be necessary for residual-free resist removal.

Low-boiling solvents are theoretically also suitable as strippers, but because of the impossibility of their use at higher temperatures, they are restricted in their performance.

**Suitable Lift-off Media**

For the lift-off, the same recommendations apply, with the exception of the AZ® 100 remover, which is not a well suited media for this process step.

**Areas of Application of Negative Resist**

**AZ® nLOF 2000**

The AZ® nLOF 2000 negative resist series is optimised for lift-off applications. In the resist film thickness range of approximately 1 to 15 µm, an undercut which can be adjusted to a limited extent can be attained, which becomes increasingly progressive in the case of larger resist thicknesses (Fig. 108) since hereby the substrate-near resist keeps unexposed, thus non-cross-linked and soluble in the developer.

Due to their cross-linking, the resist structures are not thermally softened even at high temperatures, but the evaporation temperature should not exceed 140 - 150°C. Because the degree of cross-linking rises so high...
much that a lift off is very difficult. The TechniStrip® NI555 is advisable as a lift-off medium or stripper for strongly cross-linked resist film.

**AZ® 15 nXT**

The AZ® 15 nXT allows vertical resist sidewalls in the range of approx. 5 - 25 μm of resist film thickness. Due to its high chemical stability and good adhesion to conventional substrate materials, it is particularly suitable for electroplating. For highly cross-linked resist films, the TechniStrip® NI555 is recommended as a stripper.

**AZ® 125 nXT**

The AZ® 125 nXT extends the application range of the AZ® 15 nXT to resist film thicknesses of approx. 30 - 150 μm. Film thicknesses of several 100 μm can also be attained via adapted processes. For high resist film thicknesses and/or highly cross-linked resist films, the TechniStrip® P1316 or 1331 is recommended as a stripper.
Inorganic Developers

AZ® Developer is based on sodium phosphate and –metasilicate, is optimized for minimal aluminum attack and is typically used diluted 1:1 in DI water for high contrast or undiluted for high development rates. The dark erosion of this developer is slightly higher compared to other developers.

AZ® 351B is based on buffered NaOH and typically used diluted 1:4 with water, for thick resists up to 1:3 if a lower contrast can be tolerated.

AZ® 400K is based on buffered KOH and typically used diluted 1:4 with water, for thick resists up to 1:3 if a lower contrast can be tolerated.

AZ® 303 specifically for the AZ® 111 XFS photoresist based on KOH / NaOH is typically diluted 1:3 - 1:7 with water, depending on whether a high development rate, or a high contrast is required.

Metal Ion Free (TMAH-based) Developers

AZ® 326 MIF is 2.38 % TMAH- (Tetramethylammoniumhydroxide) in water.

### Our Developers: Application Areas and Compatibilities

Inorganic Developers

(typical demand under standard conditions approx. 20 L developer per L photoresist)

AZ® Developer is based on sodium phosphate and –metasilicate, is optimized for minimal aluminum attack and is typically used diluted 1:1 in DI water for high contrast or undiluted for high development rates. The dark erosion of this developer is slightly higher compared to other developers.

AZ® 351B is based on buffered NaOH and typically used diluted 1:4 with water, for thick resists up to 1:3 if a lower contrast can be tolerated.

AZ® 400K is based on buffered KOH and typically used diluted 1:4 with water, for thick resists up to 1:3 if a lower contrast can be tolerated.

AZ® 303 specifically for the AZ® 111 XFS photoresist based on KOH / NaOH is typically diluted 1:3 - 1:7 with water, depending on whether a high development rate, or a high contrast is required.

Metal Ion Free (TMAH-based) Developers

(typical demand under standard conditions approx. 5 - 10 L developer concentrate per L photoresist)

AZ® 326 MIF is 2.38 % TMAH- (Tetramethylammoniumhydroxide) in water.
Our frequently updated wafer stock list can be found here:

AZ® 726 MIF is 2.38 % TMAH- (TetraMethylAmmonium Hydroxide) in water, with additional surfactants for rapid and uniform wetting of the substrate (e. g. for puddle development).
AZ® 826 MIF is 2.38 % TMAH- (TetraMethylAmmonium Hydroxide) in water, with additional surfactants for rapid and uniform wetting of the substrate (e. g. for puddle development) and other additives for the removal of poorly soluble resist components (residues with specific resist families), however at the expense of a slightly higher dark erosion.

---

**Our Removers: Application Areas and Compatibilities**

**AZ® 100 Remover** is an amine solvent mixture and standard remover for AZ® and TI photoresists. To improve its performance, AZ® 100 remover can be heated to 60 - 80°C. Because the AZ® 100 Remover reacts highly alkaline with water, it is suitable for this with respect to sensitive substrate materials such as Cu, Al or ITO only if contamination with water can be ruled out..

**TechniStrip® P1316** is a remover with very strong stripping power for Novolak-based resists (including all AZ® positive resists), epoxy-based coatings, polyimides and dry films. At typical application temperatures around 75°C, TechniStrip® P1316 may dissolve cross-linked resists without residue also, e.g. through dry etching or ion implantation. TechniStrip® P1316 can also be used in spraying processes. For alkaline sensitive materials, TechniStrip® P1313 would be an alternative to the P1316. Nicht kompatibel mit Au oder GaAs.

**TechniStrip® P1331** can be an alternative for TechniStrip® P1316 in case of alkaline sensitive materials. TechniStrip® P1331 is not compatible with Au or GaAs.

**TechniStrip® N1555** is a stripper with very strong dissolving power for Novolak-based negative resists such as the AZ® 15 nXT and AZ® nLOF 2000 series and very thick positive resists such as the AZ® 40 XT. TechniStrip® N1555 was developed not only to peel cross-linked resists, but also to dissolve them without residues. This prevents contamination of the basin and filter by resist particles and skins, as can occur with standard strippers. TechniStrip® N1555 is not compatible with Au or GaAs.

**TechniClean™ CA25** is a semi-aqueous proprietary blend formulated to address post etch residue (PER) removal for all interconnect and technology nodes. Extremely efficient at quickly and selectively removing organo-metal oxides from Al, Cu, Ti, TiN, W and Ni.

**TechniStrip™ NFS2** is a highly effective remover for negative resists (liquid resists as well as dry films). The intrinsic nature of the additives and solvent make the blend totally compatible with metals used throughout the BEOL interconnects to WLP bumping applications.

**TechniStrip™ Micro D2** is a versatile stripper dedicated to address resin lift-off and dissolution on negative and positive tone resist. The organic mixture blend has the particularity to offer high metal and material compatibility allowing to be used on all stacks and particularly on fragile III/V substrates for instance.

**TechniStrip™ MLO 07** is a highly efficient positive and negative tone photoresist remover used for IR, III/V, MEMS, Photonic, TSV mask, solder bumping and hard disk stripping applications. Developed to address high dissolution performance and high material compatibility on Cu, Al, Sn/Ag, Alumina and common organic substrates.

---

**Our Wafers and their Specifications**

**Silicon-, Quartz-, Fused Silica and Glass Wafers**

Silicon wafers are either produced via the Czochralski- (CZ-) or Float zone- (FZ-) method. The more expensive FZ wafers are primarily reasonable if very high-ohmic wafers (> 100 Ohm cm) are required.

Quartz wafers are made of monocrystalline SiO$_2$, main criterion is the crystal orientation (e. g. X-, Y-, Z-, AT- or ST-cut).

Fused silica wafers consist of amorphous SiO$_2$. The so-called JGS2 wafers have a high transmission in the range of $\approx$ 280 - 2000 nm wavelength, the more expensive JGS1 wafers at $\approx$ 220 - 1100 nm.

Our glass wafers, if not otherwise specified, are made of borosilicate glass.

**Specifications**

Common parameters for all wafers are diameter, thickness, and uniformity (1- or 2-side polished). Fused silica wafers are made either of JGS1 or JGS2 material, for quartz wafers the crystal orientation needs to be defined.

**Prime-, Test-, and Dummy Wafers**

Silicon wafers usually come as „Prime-grade” or „Test-grade”, latter mainly have a slightly broader particle specification. „Dummy-Wafers” neither fulfill Prime- nor Test-grade for different possible reasons (e. g. very broad or missing specification of one or several parameters, reclaim wafers, no particle specification) but might be a cheap alternative for e. g. resist coating tests or equipment start-up.

Further Information

Our Photolithography Book and -Posters

We see it as our main task to make you understand all aspects of microstructuring in an application-oriented way. At present, we have implemented this claim with our book Photolithography on over 200 pages, as well as attractively designed DIN A0 posters for your office or laboratory.

We will gladly send both of these to you free of charge as our customer (if applicable, we charge shipping costs for non-European deliveries):
www.microchemicals.com/downloads/brochures.html
www.microchemicals.com/downloads/posters.html
Thank you for your interest!
